17

Construct the probability distribution for $X$, the probability for the total number of people that can attend two distinct games

# $\mathrm{P}(\mathrm{X})$, attendance at 2 hockey games 

Maximum Attendance<br>(thousands)<br>$19+16=35$

Teams
Devils/Islanders

## So here we found $X=35$,

Find the rest and then calculate $P(X)$ for all $X$

How many possible $X$ values will we have?

# $\mathrm{P}(\mathrm{X})$, attendance at 2 hockey games 

## Maximum Attendance <br> (thousands) <br> $19+16=35$

Teams
Devils/Islanders

How many possible $X$ values will we have? We are selecting 2 arenas out of 5

The number of $X$ values is

$$
\binom{5}{2}=\frac{5!}{3!2!}=\frac{5 * 4 * 3 * 2 * 1}{3 * 2 * 1 * 2 * 1}=10
$$

## $\mathrm{P}(\mathrm{X})$, attendance at 2 hockey games

Teams

## What do you think is the average number of cars per household?

Vehicles per Household, $x$

| 0 | 0.087 |
| :--- | :--- |
| 1 | 0.331 |
| 2 | 0.381 |
| 3 | 0.201 |

## What do you think is the average number of cars per household?

\author{

Vehicles per <br> Household, $x$ <br> | 0 | 0.087 |
| :--- | :--- |
| 1 | 0.331 |
| 2 | 0.381 |
| 3 | 0.201 |

}

Average $=0$ * $0.087+1$ * $0.331+2 * 0.381+3 * 0.201=$ 1.696

## In a more abstract way

$$
\text { Average }=\text { Sum over all }\left(X^{*} \mathrm{P}(\mathrm{X})\right)
$$

The mean of a probability distribution for the random variable $X$ is called its expected value and is denoted by $\mu_{X}$ or $E(X)$.

The mean gets called expected value of the distribution Sometimes indicated as $\mathrm{E}(\mathrm{X})$ or $\mu_{\mathrm{x}}$

## Getting insured

The probability that you get burglarized is 26.9 per 1000 people

| Outcome | Payout, $x$ | Probability, $p$ | $x \cdot p$ |
| :--- | :---: | :---: | :---: |
| No burglary | 0 | 0.9731 | 0 |
| Burglary | 5000 | 0.0269 | 134.50 |
|  |  |  |  |
|  |  |  |  |
|  |  |  |  |

What the company will pay is $\$ 5,000$

## Getting insured

The expected payout the company will pay is
0 if there are no burglaries $\$ 5000$ if there is a burglary

For each policy we will pay on average $0 * 0+5000$ *0.0269

Outcome
No burglary
Burglary
Payout, $x$
0
5000

$$
=\operatorname{Sum}(X * P(X))=134.50
$$

## Getting insured

The company will break even if they charge 134.50
$97 \%$ of the time people will pay, not be burglarized and not get anything,

The rest of the time they will be burglarized and get 5 K
The company breaks even, since

$$
E(X)=X P(X)
$$

What everyone pays = What the company pays

## The Wisconsin lottery

Winnings, $x$

| $\$ 1$ | $1 / 10$ |
| ---: | :--- |
| $\$ 2$ | $1 / 14$ |
| $\$ 3$ | $1 / 24$ |
| $\$ 18$ | $1 / 200$ |
| $\$ 50$ | $1 / 389$ |
| $\$ 150$ | $1 / 20,000$ |
| $\$ 900$ | $1 / 120,000$ |

A ticket costs $\$ 1$.
Why don't the probabilities add to one?
What is missing?

## The Wisconsin lottery

| Winnings, $x$ | Probability, $p$ |
| :---: | :--- |
| $\$ 1$ | $1 / 10$ |
| $\$ 2$ | $1 / 14$ |
| $\$ 3$ | $1 / 24$ |
| $\$ 18$ | $1 / 200$ |
| $\$ 50$ | $1 / 389$ |
| $\$ 150$ | $1 / 20,000$ |
| $\$ 900$ | $1 / 120,000$ |

What is the expected value for the probability distribution?

## The Wisconsin lottery

| Winnings, $x$ | Probability, $p$ |
| :---: | :--- |
| $\$ 1$ | $1 / 10$ |
| $\$ 2$ | $1 / 14$ |
| $\$ 3$ | $1 / 24$ |
| $\$ 18$ | $1 / 200$ |
| $\$ 50$ | $1 / 389$ |
| $\$ 150$ | $1 / 20,000$ |
| $\$ 900$ | $1 / 120,000$ |

$$
\mathrm{P}(0)=1 \text { - Sum of the above }=0.7793
$$

$$
\mu_{x}=0.6014
$$

If we spend $\$ 1$ we will get back, on average, 60 cents.

## The Wisconsin lottery

We are given 10 tickets.
How much do we expect to win?
0.6014 for each ticket

10* $0.6014=\$ 6.01$ for 10 tickets

## Calculate the expected value

| Value, $x$ | Frequency, $f$ |  |
| :---: | :---: | :---: |
| 5 | 12 |  |
| 6 | 23 |  |
| 8 | 15 |  |
|  |  | There are <br> $\mathrm{n}=50$ |
| Value, $\boldsymbol{x}$ | Proportion, $\boldsymbol{f} / \boldsymbol{n}$ | outcomes |
| 5 | 0.24 |  |
| 6 | $?$ |  |

## Calculate the expected value

Value, $x$ 5

12
6
23
8
15
Frequency, $f$
outcomes

Proportion, $f / n$
0.24
?
?
There are

$$
\mathrm{n}=50
$$

$$
\mu_{x}=\sum\left(x \frac{f}{n}\right)
$$

$$
\sim 6.3
$$

### 6.2 Variances of Probability distributions

$$
\begin{aligned}
& \sigma_{n}^{2}=\sum \frac{(x-\bar{x})^{2}}{n} \\
& S D=\sqrt{\sigma_{n}^{2}}=\sqrt{\sum \frac{(x-\bar{x})^{2}}{n}}
\end{aligned}
$$

For a set of data - note the n instead of $\mathrm{n}-1$

# 6.2 Variances of Probability distributions 

For a probability distribution $\mathrm{P}(\mathrm{X})$

$$
\begin{aligned}
& \sigma_{x}^{2}=\sum \frac{(x-\bar{x})^{2}}{n} \\
& S D=\sqrt{\sigma_{n}^{2}}=\sqrt{\sum \frac{(x-\bar{x})^{2}}{n}}
\end{aligned}
$$

## Try calculating the variance and SD

| Winnings, $x$ | Probability, $p$ |
| :---: | :--- |
| $\$ 1$ | $1 / 10$ |
| $\$ 2$ | $1 / 14$ |
| $\$ 3$ | $1 / 24$ |
| $\$ 18$ | $1 / 200$ |
| $\$ 50$ | $1 / 389$ |
| $\$ 150$ | $1 / 20,000$ |
| $\$ 900$ | $1 / 120,000$ |

Recall, the average is 60.14 cents or 0.6014 dollars

## Try calculating the variance and SD

| Winnings, $x$ | Probability, $p$ |
| :---: | :--- |
| $\$ 1$ | $1 / 10$ |
| $\$ 2$ | $1 / 14$ |
| $\$ 3$ | $1 / 24$ |
| $\$ 18$ | $1 / 200$ |
| $\$ 50$ | $1 / 389$ |
| $\$ 150$ | $1 / 20,000$ |
| $\$ 900$ | $1 / 120,000$ |

The way to think about this is: for each deviation from the mean, what is the probability? For example The contribution for the $\$ 1$ winning is

$$
(1-0.6014)^{2} * 1 / 10
$$

## Try calculating the variance and SD

| Winnings, $x$ | Probability, $p$ |
| :---: | :--- |
| $\$ 1$ | $1 / 10$ |
| $\$ 2$ | $1 / 14$ |
| $\$ 3$ | $1 / 24$ |
| $\$ 18$ | $1 / 200$ |
| $\$ 50$ | $1 / 389$ |
| $\$ 150$ | $1 / 20,000$ |
| $\$ 900$ | $1 / 120,000$ |

So all together, the variance is
$(1-0.6014)^{2} * 1 / 10+(2-0.6014)^{2} * 1 / 14+$ etc etc $=16.32$
The standard deviation is its square root $=\$ 4.04$

## Variances

## Formula for the Variance of a Probability Distribution

The variance of a discrete probability distribution is given by

$$
\operatorname{Var}(X)=\sigma_{X}^{2}=\sum\left(x-\mu_{X}\right)^{2} \cdot p
$$

Here, $p$ is the probability that the random variable $X$ takes on the specific value $x$ and $\mu_{X}$ is the expected value. To get the standard deviation, take the square root of the variance.

## Significance

The average payout is $\$ 0.60$ With a SD of $\$ 4.04$

This means on average you win little but there is a chance of winning a lot (that is why the SD is large)

## Let's triple the lottery

| Original <br> Winnings, $x$ | Winnings in Special <br> Promotion, $3 x$ | Probability, $p$ |
| :---: | :---: | :---: |
| $\$ 0$ | $\$ 0$ | 0.7793 |
| $\$ 1$ | $\$ 3$ | $1 / 10$ |
| $\$ 2$ | $\$ 6$ | $1 / 14$ |
| $\$ 3$ | $\$ 9$ | $1 / 24$ |
| $\$ 18$ | $\$ 54$ | $1 / 200$ |
| $\$ 50$ | $\$ 150$ | $1 / 389$ |
| $\$ 150$ | $\$ 450$ | $1 / 20,000$ |
| $\$ 900$ | $\$ 2700$ | $1 / 120,000$ |

Calculate mean and standard deviation Compare to original lottery

## Let's triple the lottery

Original lottery winnings $\$ 0.6014$ New winnings $\$ 1.804$

Is this smart on Wisconsin's part?

$$
\begin{gathered}
\text { Original SD }=\$ 4.04 \\
\text { New SD }=\$ 12.12
\end{gathered}
$$

How are they related?
They are both multiplied by 3 !

$$
\mathrm{SD}=\sigma_{\mathrm{x}}
$$

## Let's triple the lottery

$\mu_{x}$ turns into $3 \mu_{x}$
$\sigma_{x}$ turns into $3 \sigma_{x}$

This is true in general. Multiplying data will rescale average and SD of the distribution

What if I had decided to add 50 cents to each winning?

# Let's add 50 cents to the payout 

$\mu_{\mathrm{x}}$ turns into $0.50+\mu_{\mathrm{x}}$

$$
\sigma_{X} \text { stays } \sigma_{X}
$$

## Just like rescaling and recentering

 So, adding C and multiplying by D gives$$
\begin{array}{r}
\mu_{\mathrm{x}} \text { turns into } \mu_{\mathrm{C}+\mathrm{DX}}=\mathrm{C}+\mathrm{D}^{*} \mu_{\mathrm{x}} \\
\sigma_{\mathrm{X}} \text { turns into } \sigma_{\mathrm{C}+\mathrm{DX}}=\mathrm{D}^{*} \sigma_{\mathrm{X}}
\end{array}
$$

## In general

## Linear Transformation Rule: The Effect of a Linear Transformation of $X$ on $\mu_{X}$ and $\sigma_{X}$

Suppose you have a probability distribution for random variable $X$, with mean $\mu_{X}$ and standard deviation $\sigma_{X}$. If you transform each value by multiplying it by $d$ and then adding $c$, where $c$ and $d$ are constants, then the mean and the standard deviation of the transformed values are given by

$$
\begin{aligned}
& \mu_{c+d x}=c+d \mu_{x} \\
& \sigma_{c+d x}=|d| \sigma_{X}
\end{aligned}
$$

Now, this was for TRIPLING the lottery
What if we kept the same lottery and bought 3 tickets?

## What do you think?

If every time I play my average payout is $\$ 0.6014$ What do I get after buying 3 tickets?

## What do you think?

If every time I play my average payout is $\$ 0.6014$ What do I get after buying 3 tickets?

$$
\text { Duh }-3 \text { * } 0.6014=1.804!
$$

## Just like before!

It does not matter if I triple the lottery or if I buy three tickets, the result is the same.

My take-home on average is tripled.

## What do you think?

We can conclude that when we select three items from the same distribution we find

$$
\mu_{3, x}=3 \mu_{x}=\mu_{x}+\mu_{x}+\mu_{x}
$$

In general, for different distributions we get

$$
\mu_{X, Y}=\mu_{x}+\mu_{y}
$$

## Two tickets from two lotteries

Let's buy a ticket from the lottery of California and of Texas

> California $\mu_{\mathrm{x}}=\$ 0.50$
> Texas $\mu_{\mathrm{Y}}=\$ 0.75$

What are the expected total winnings?

$$
\mu_{\mathrm{CA}, \mathrm{TX}}=\mu_{\mathrm{CA}}+\mu_{\mathrm{TX}}=\$ 0.50+\$ 0.75=\$ 1.25
$$

## What about the standard deviation?

We will look at that next time.

## Practice and hk
