## Chapter 4

## Solutions to Supplementary Check for Understanding Problems

## Energy Changes

1. Indicate whether each of the following involves primarily kinetic energy or potential energy.
a) stretched rubber band
b) running water
c) stack of books
d) person riding a bike
e) car parked on a hill
f) pitched baseball

Answers:
a) potential energy
d) kinetic energy
b) kinetic energy
e) potential energy
c) potential energy
f) kinetic energy

## Solutions

Kinetic energy is associated with motion as is found in (b), (d) and (f). Potential energy is stored energy associated with the position of an object as in (a), (c) and (e).
2. Which physical state involves constituent particles with the highest kinetic energy?

## Solution

The gas phase is associated with constituent particles having the highest kinetic energy because energy must be added as a substance moves from the solid state to the liquid state to the gas phase. This added energy is causes the constituent particles to move faster.
3. Is the condensation of a gas an exothermic or endothermic process? Explain.

Answer: exothermic

## Solution

An exothermic process is one in which energy (heat) is released. The liquid state is at a lower energy level than the gas phase so energy is released as a gas condenses. It is helpful to note that the reverse process (liquid $\rightarrow$ gas) is endothermic because it requires an input of heat.
4. How much energy (in kJ ) is needed to heat 3.8 L of water from $22.3^{\circ} \mathrm{C}$ to $100{ }^{\circ} \mathrm{C}$ ?

Answer: $\quad 1.2 \times 10^{3} \mathrm{~kJ}$

## Solution

The amount of heat energy (q) needed is calculated from $q=m \cdot c \cdot \Delta t$. For water, the specific heat (c) equals $4.18 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$. The temperature change $(\Delta \mathrm{t})$ is $100{ }^{\circ} \mathrm{C}-22.3^{\circ} \mathrm{C}=77.7^{\circ} \mathrm{C}$. The mass of water (m) in grams must be calculated from its volume using the density of water (in Table 2.3 the water density $=0.9978 \mathrm{~g} / \mathrm{mL}$ at $22^{\circ} \mathrm{C}$ ). The solution map for this conversion is:

$$
\mathrm{L} \mathrm{H}_{2} \mathrm{O} \rightarrow \mathrm{~mL} \mathrm{H}_{2} \mathrm{O} \rightarrow \mathrm{~g} \mathrm{H}_{2} \mathrm{O}
$$

This yields:
$3.8 \mathrm{LH}_{2} \mathrm{O} \times \frac{1 \mathrm{mLH}_{2} \mathrm{O}}{10^{-3} \mathrm{LH}_{2} \mathrm{O}} \times \frac{0.9978 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}{1 \mathrm{mLH}_{2} \mathrm{O}}=3.8 \times 10^{3} \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$
Substituting these values and calculating $q$ gives:

$$
\begin{gathered}
\mathrm{q}=\left(3.8 \times 10^{3} \mathrm{H}_{2} \mathrm{O}\right)\left(4.18 \mathrm{~J} / \mathrm{H}_{2} \mathrm{O} \times{ }^{\circ} \mathrm{C}\right)\left(77.7{ }^{\circ} \mathrm{C}\right)=1.2 \times 10^{6} \mathrm{~J} \\
1.210^{6} \mathrm{~J} \times \frac{1 \mathrm{~kJ}}{10^{3} \mathrm{~J}}=1.2 \times 10^{3} \mathrm{~kJ}
\end{gathered}
$$

5. When 25 g of water freezes 8.4 kJ of energy is released. How much energy is required to melt a pound of ice?

Answer: $\quad 1.5 \times 10^{2} \mathrm{~kJ}$

## Solution

Note that is takes 8.4 kJ to melt 25 g of water so this serves as the conversion factor between grams of water and energy. The solution map is:

$$
\begin{gathered}
\mathrm{lb} \mathrm{H}_{2} \mathrm{O} \rightarrow \mathrm{~g} \mathrm{H} \mathrm{H}_{2} \mathrm{O} \rightarrow \mathrm{~kJ} \\
1 \mathrm{HbH}_{2} \mathrm{O} \times \frac{454 \mathrm{~g}_{2} \mathrm{O}}{1+\mathrm{bH}_{2} \mathrm{O}} \times \frac{8.4 \mathrm{~kJ}}{25 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}}=1.5 \times 10^{2} \mathrm{~kJ}
\end{gathered}
$$

6. Calculate the specific heat of a solid $\left(\mathrm{J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}\right)$ if 118 kcal of energy are needed to raise the temperature of 12.7 kg of the solid from $24^{\circ} \mathrm{C}$ to $327^{\circ} \mathrm{C}$ ?

Answer: $\quad 0.128 \mathrm{~J} / \mathrm{g} \cdot{ }^{\circ} \mathrm{C}$

## Solution

The specific heat (c) can be calculated by rearranging equation 4.1 to give:

$$
c=\frac{q}{m \Delta t}
$$

The amount of heat added (q) is 118 kcal which must be converted to joules. Recall that 1 cal equals exactly 4.184 J . The solution map is:

$$
\begin{aligned}
& \text { kcal } \rightarrow \mathrm{cal} \rightarrow \mathrm{~J} \\
& 118 \text { keal } \times \frac{10^{3} \mathrm{eat}}{1 \text { keal }} \times \frac{4.184 \mathrm{~J}}{1 \text { eal }}=4.94 \times 10^{5} \mathrm{~J}
\end{aligned}
$$

The mass of the substance is 12.7 kg or $12.7 \times 10^{3} \mathrm{~g}$, and the temperature change $(\Delta \mathrm{t})$ is $327^{\circ} \mathrm{C}$ $24{ }^{\circ} \mathrm{C}=303{ }^{\circ} \mathrm{C}$. Substituting these values and calculating c gives:

$$
c=\frac{4.94 \times 10^{5} \mathrm{~J}}{\left(12.7 \times 10^{3} \mathrm{~g}\right)\left(303^{\circ} \mathrm{C}\right)}=0.128 \frac{\mathrm{~J}}{\mathrm{~g} \cdot{ }^{\circ} \mathrm{C}}
$$

7. If a $10-\mathrm{g}$ sample of copper and a $10-\mathrm{g}$ sample of aluminum are placed in a large container of boiling water for several minutes than then removed and quickly transferred to a large container of ice water, which metal will lose the greater amount of energy? Explain.

Answer: aluminum

## Solution

The amount of heat energy lost is calculated from $q=m \cdot c \cdot \Delta t$. Since the masses are the same $(10 \mathrm{~g})$ and $\Delta t$ is the same $\left(100{ }^{\circ} \mathrm{C}-0^{\circ} \mathrm{C}=100^{\circ} \mathrm{C}\right)$, $q$ will be larger for the metal with the larger specific heat which is aluminum.
8. When you enter a room having a uniform temperature and touch a metal object it feels cooler than when you touch a wooden object in the room. What is your explanation (hypothesis) for this difference? What simple experiments could you do to test your hypothesis?

## Solution

Hypothesis: Assuming both objects have been in the room for some time they should both be at room temperature. Because you are warmer than room temperature, heat leaves your body when you touch either object. Heat is transferred at a faster rate (your skin cools faster) when you touch the metal object than it does when you touch the wooden object because metals conduct heat much better (faster) than objects made of wood or plastic (mostly composed of nonmetals) so it feels like the metal object is cooler.

Experiment: One way to compare the ability of different materials to conduct heat is to have two containers at different temperatures connected by a sample of each material you wish to test. You could use a pot of boiling water for the higher temperature and an ice cube (or other ice mold) for the lower temperature. The samples of different materials should be exactly the same in size and shape (see figure below).

When this arrangement is created, heat will be transferred from the boiling water to the ice. By measuring the time it takes to melt the ice, or how much ice melts in a given time, you can determine which materials conduct heat more effectively.

## Chemical Reactions

1. Convert each of the following word equations into a chemical equation and then balance it. Indicate the physical state of each reactant and product.
a) phosphoric acid + calcium hydroxide $\rightarrow$ water + calcium phosphate
b) ammonium nitrate $\rightarrow$ nitrogen gas + water + oxygen gas

Answers:
a) $2 \mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{aq})+3 \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s}) \rightarrow 6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s})$
b) $2 \mathrm{NH}_{4} \mathrm{NO}_{3}(\mathrm{~s}) \rightarrow 2 \mathrm{~N}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g})$

## S.4.7 CHAPTER 4 SOLUTIONS TO SUPPLEMENTARY CHECK FOR UNDERSTANDING PROBLEMS

## Solutions

First, write the chemical formula for each reactant and product, along with its physical state. Then use whole-number coefficients in front of the reactant/product formulas to balance atoms on both sides of the equation.
a) Reactant formulas:
phosphoric acid - The name indicates an oxoacid (no hydro- prefix) based on the anion phosphate $\left(\mathrm{PO}_{4}{ }^{3-}\right)$. Thus, three $\mathrm{H}^{+}$ions are needed to balance by the charge on the anion and the correct formula is $\mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{aq})$. Note that oxoacids are generally used as an aqueous solution and are rarely used in pure form.
calcium hydroxide - The metal cation is $\mathrm{Ca}^{2+}$. The polyatomic anion formula is $\mathrm{OH}^{-}$. It takes two hydroxides to balance the charge on the cation so the compound formula is $\mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s})$. The solid state is used since there is no information to suggest that this is not the pure compound.

Product formulas:
water - $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
calcium phosphate - The metal cation is $\mathrm{Ca}^{2+}$. The anion formula is $\mathrm{PO}_{4}{ }^{3-}$. Use the value of the anion charge as the subscript for the cation and use the value of the cation charge as the subscript for the anion. The compound formula is $\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. This ionic compound is formed in the presence of water so you must consider if this compound dissolves readily in water. The combination of +2 and -3 ion charges suggest this will be an insoluble compound so the solid state is used.

This results in the equation:

$$
\mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{aq})+\mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s})
$$

Notice that the polyatomic phosphate ion does not undergo any change in composition in this reaction. This means that you can balance $\mathrm{PO}_{4}{ }^{3-}$ units just like an individual atom. Since there are 2 phosphate ions on the product side, a coefficient of 2 is needed in front of $\mathrm{H}_{3} \mathrm{PO}_{4}$ on the reactant side. To balance calcium atoms, place a coefficient of 3 in front of $\mathrm{Ca}(\mathrm{OH})_{2}$ on the reactant side. There are now 12 hydrogen atoms on the reactant side and only 2 on the product side so a cooefficient of 6 is needed in front of water on the product side. Notice that this also balances the oxygen atoms, a total of 14 on each side of the equation. The balanced equation is:

$$
2 \mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{aq})+3 \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s}) \rightarrow 6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s})
$$

## S.4.8 CHAPTER 4 SOLUTIONS TO SUPPLEMENTARY CHECK FOR UNDERSTANDING PROBLEMS

b) Reactant formula:
ammonium nitrate - The metal cation is $\mathrm{NH}_{4}^{+}$. The polyatomic anion formula is $\mathrm{NO}_{3}{ }^{-}$. Since the ion charges are the same, it takes one cation to balance the charge on the anion and the compound formula is $\mathrm{NH}_{4} \mathrm{NO}_{3}$. A pure ionic compound is expected to be a solid.

Product formulas:
nitrogen gas - This element exists as a diatomic molecule with the formula $\mathrm{N}_{2}(\mathrm{~g})$.
water - $\mathrm{H}_{2} \mathrm{O}(1)$
oxygen gas - This element exists as a diatomic molecule with the formula $\mathrm{O}_{2}(\mathrm{~g})$.
This results in the unbalanced equation

$$
\mathrm{NH}_{4} \mathrm{NO}_{3}(\mathrm{~s}) \rightarrow \mathrm{N}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \quad(\mathrm{N} \text { and } \mathrm{O} \text { atoms balanced })
$$

Notice that the nitrogen atoms and oxygen atoms are balanced, so balance the hydrogen atoms. Place a coefficient of 2 in front of $\mathrm{H}_{2} \mathrm{O}$ to balanced hydrogen atoms, but now there are 3 oxygen atoms on the reactant side and four on the product side.

$$
\mathrm{NH}_{4} \mathrm{NO}_{3}(\mathrm{~s}) \rightarrow \mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \quad(\mathrm{N} \text { and } \mathrm{H} \text { atoms balanced })
$$

A coefficient of $1 / 2$ in front of $\mathrm{O}_{2}$ will balance oxygen atoms.

$$
\mathrm{NH}_{4} \mathrm{NO}_{3}(\mathrm{~s}) \rightarrow \mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+1 / 2 \mathrm{O}_{2}(\mathrm{~g}) \quad \text { (all atoms balanced) }
$$

The fractional coefficient in front of $\mathrm{O}_{2}$ can be converted to the smallest whole number by multiplying by 2 . This requires that all other coefficients be multiplied by 2 in order to retain the atom balance. The resulting balanced equation is:

$$
2 \mathrm{NH}_{4} \mathrm{NO}_{3}(\mathrm{~s}) \rightarrow 2 \mathrm{~N}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g})
$$

2. Balance each of the following chemical equations.
a) $\mathrm{CaC}_{2}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s})+\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})$
b) $\mathrm{NO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{HNO}_{3}(\mathrm{aq})+\mathrm{NO}(\mathrm{g})$
c) $\mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+\mathrm{CO}(\mathrm{s}) \rightarrow \mathrm{Fe}(\mathrm{s})+\mathrm{CO}_{2}(\mathrm{~g})$
d) $\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g})$

Answers:
a) $\mathrm{CaC}_{2}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s})+\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})$
b) $3 \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow 2 \mathrm{HNO}_{3}(\mathrm{aq})+\mathrm{NO}(\mathrm{g})$
c) $\mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+3 \mathrm{CO}(\mathrm{s}) \rightarrow 2 \mathrm{Fe}(\mathrm{s})+3 \mathrm{CO}_{2}(\mathrm{~g})$
d) $2 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g})$

Solutions
a) Initially the carbon atoms and calcium atoms are balanced but the hydrogen and oxygen atoms are not.

$$
\begin{aligned}
& \mathrm{CaC}_{2}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s})+\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g}) \\
& 2 \text { atoms } \leftarrow \mathrm{C} \rightarrow 2 \text { atoms } \\
& 1 \text { atom } \leftarrow \mathrm{Ca} \rightarrow 1 \text { atom } \\
& 2 \text { atoms } \leftarrow \mathrm{H} \rightarrow 4 \text { atoms } \\
& 1 \text { atom } \leftarrow \mathrm{O} \rightarrow 2 \text { atoms }
\end{aligned}
$$

Placing a coefficient of 2 in front of water will balance both the hydrogen and oxygen atoms.

$$
\mathrm{CaC}_{2}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s})+\mathrm{C}_{2} \mathrm{H}_{2}(\mathrm{~g})
$$

b) Initially no atoms are balanced.

$$
\begin{aligned}
& \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{HNO}_{3}(\mathrm{aq})+\mathrm{NO}(\mathrm{~g}) \\
& 1 \text { atom } \leftarrow \mathrm{N} \rightarrow 2 \text { atoms } \\
& 2 \text { atoms } \leftarrow \mathrm{H} \rightarrow 1 \text { atom } \\
& 3 \text { atoms } \leftarrow \mathrm{O} \rightarrow 4 \text { atoms }
\end{aligned}
$$

Also note that any new coefficient will change the number of two or three different atoms. Start by placing a coefficient of 2 in front of $\mathrm{HNO}_{3}$ to balance the hydrogen atoms. This results in the following.

$$
\begin{aligned}
& \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow 2 \mathrm{HNO}_{3}(\mathrm{aq})+\mathrm{NO}(\mathrm{~g}) \\
& 1 \text { atom } \leftarrow \mathrm{N} \rightarrow 3 \text { atoms } \\
& 2 \text { atoms } \leftarrow \mathrm{H} \rightarrow 2 \text { atoms } \\
& 3 \text { atoms } \leftarrow \mathrm{O} \rightarrow 7 \text { atoms }
\end{aligned}
$$

Next place a coefficient of 3 in front of $\mathrm{NO}_{2}$ to balance the nitrogen atoms. This also balances the oxygen atoms and results in a balanced equation.

$$
\begin{gathered}
3 \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow 2 \mathrm{HNO}_{3}(\mathrm{aq})+\mathrm{NO}(\mathrm{~g}) \\
3 \text { atoms } \leftarrow \mathrm{N} \rightarrow 3 \text { atoms } \\
2 \text { atoms } \leftarrow \mathrm{H} \rightarrow 2 \text { atoms } \\
7 \text { atoms } \leftarrow \mathrm{O} \rightarrow 7 \text { atoms }
\end{gathered}
$$

c) Initially only the carbon atoms are balanced.

$$
\begin{aligned}
& \mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+\mathrm{CO}(\mathrm{~s}) \rightarrow \mathrm{Fe}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \\
& 1 \text { atom } \leftarrow \mathrm{C} \rightarrow 1 \text { atom } \\
& 2 \text { atoms } \leftarrow \mathrm{Fe} \rightarrow 1 \text { atom } \\
& 4 \text { atoms } \leftarrow \mathrm{O} \rightarrow 2 \text { atoms }
\end{aligned}
$$

Placing a coefficient of 2 in front of Fe will balance the iron atoms.

$$
\begin{aligned}
& \mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+\mathrm{CO}(\mathrm{~s}) \\
& \rightarrow 2 \mathrm{Fe}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \\
& 1 \text { atom } \leftarrow \mathrm{C} \rightarrow 1 \text { atom } \\
& 2 \text { atoms } \leftarrow \mathrm{Fe} \rightarrow 2 \text { atoms } \\
& 4 \text { atoms } \leftarrow \mathrm{O} \rightarrow 2 \text { atoms }
\end{aligned}
$$

Any attempt to add more oxygen atoms to the product side by changing the coefficient in front of $\mathrm{CO}_{2}$ will upset the balance of carbon atoms so the same coefficient must be placed in front of CO as well. A coefficient of 3 will balance both the oxygen atoms and carbon atoms.

$$
\begin{aligned}
& \mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+3 \mathrm{CO}(\mathrm{~s}) \rightarrow 2 \mathrm{Fe}(\mathrm{~s})+3 \mathrm{CO}_{2}(\mathrm{~g}) \\
& 3 \text { atoms } \leftarrow \mathrm{C} \rightarrow 3 \text { atoms } \\
& 2 \text { atoms } \leftarrow \mathrm{Fe} \rightarrow 2 \text { atoms } \\
& 6 \text { atoms } \leftarrow \mathrm{O} \rightarrow 6 \text { atoms }
\end{aligned}
$$

d) Initially the hydrogen atoms are balanced but the oxygen atoms are not.

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \\
& 2 \text { atoms } \leftarrow \mathrm{H} \rightarrow 2 \text { atoms } \\
& 2 \text { atoms } \leftarrow \mathrm{O} \rightarrow 3 \text { atoms }
\end{aligned}
$$

Placing a coefficient of $1 / 2$ in front of $\mathrm{O}_{2}$ will balance oxygen atoms.

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+1 / 2 \mathrm{O}_{2}(\mathrm{~g}) \\
& 2 \text { atoms } \leftarrow \mathrm{H} \rightarrow 2 \text { atoms } \\
& 2 \text { atoms } \leftarrow \mathrm{O} \rightarrow 2 \text { atoms }
\end{aligned}
$$

The fractional coefficient in front of $\mathrm{O}_{2}$ can be converted to the smallest whole number by multiplying by 2 . This requires that all other coefficients be multiplied by 2 in order to retain the atom balance. The resulting balanced equation is:

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g})
$$

3. If ammonia gas and 0.128 g of hydrogen chloride gas react to form 0.188 g of ammonium chloride, what mass of ammonia reacted?

Answer: $\quad 0.060 \mathrm{~g}$

## Solution

The given information is:

$$
\begin{aligned}
\mathrm{NH}_{4}(\mathrm{~g})+ & \mathrm{HCl}(\mathrm{~g}) \rightarrow \\
0.128 \mathrm{~g} & \\
& 0.188 \mathrm{~g} \mathrm{H}_{4} \mathrm{Cl}(\mathrm{~s})
\end{aligned}
$$

Since one expects the mass of the products in a chemical reaction to equal the mass of the reactants, the mass of ammonia equals $0.188 \mathrm{~g}-0.128 \mathrm{~g}=0.060 \mathrm{~g}$.
4. What does the notation '(aq)' signify about a reactant or product in a chemical equation?

Solution
The (aq) designation stands for aqueous solution and indicates that the substance is dissolved in water.
5. Classify each of the following reactions as combination, decomposition, combustion, single displacement or double displacement, then complete and balance each equation. Indicate the physical state of each product.
a) $\quad \mathrm{K}_{3} \mathrm{PO}_{4}(\mathrm{aq})+\mathrm{BaCl}_{2}(\mathrm{aq}) \rightarrow$
b) $\mathrm{Al}(\mathrm{s})+\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \rightarrow$
c) $\quad \mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow$
d) $\mathrm{CuO}(\mathrm{s})+\mathrm{HNO}_{3}(\mathrm{aq}) \rightarrow$
e) $\mathrm{Al}(\mathrm{s})+\mathrm{Br}_{2}(\mathrm{l}) \rightarrow$

Answers: a) double displacement $2 \mathrm{~K}_{3} \mathrm{PO}_{4}(\mathrm{aq})+3 \mathrm{BaCl}_{2}(\mathrm{aq}) \rightarrow 6 \mathrm{KCl}(\mathrm{aq})+\mathrm{Ba}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s})$
b) single displacement $2 \mathrm{Al}(\mathrm{s})+3 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \rightarrow 3 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}(\mathrm{aq})$
c) combustion $\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}(\mathrm{l})+6 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 4 \mathrm{CO}_{2}(\mathrm{~g})+5 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
d) double displacement $\mathrm{CuO}(\mathrm{s})+2 \mathrm{HNO}_{3}(\mathrm{aq}) \rightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
e) combination $2 \mathrm{Al}(\mathrm{s})+3 \mathrm{Br}_{2}(\mathrm{l}) \rightarrow 2 \mathrm{AlBr}_{3}(\mathrm{aq})$

## Solutions

a) This reaction between two dissolved ionic compounds should suggest a double displacement reaction of the general form $\mathrm{AB}+\mathrm{CD} \rightarrow \mathrm{AD}+\mathrm{CB}$. In this case the two metal ions, potassium $\left(\mathrm{K}^{+}\right)$and barium $\left(\mathrm{Ba}^{2+}\right)$, in the reactants switch places to form an ionic compound between potassium ion and chloride ion $\left(\mathrm{Cl}^{-}\right)$and an ionic compound between barium ion and phosphate ion $\left(\mathrm{PO}_{4}{ }^{3-}\right)$. Therefore, the product formulas are KCl and $\mathrm{Ba}_{3}\left(\mathrm{PO}_{4}\right)_{2}$. The combination of $\mathrm{a}+1$ cation and a -1 anion is expected to soluble while the combination of a +2 cation and a -3 anion is expected to insoluble. This results in the unbalanced equation:

$$
\mathrm{K}_{3} \mathrm{PO}_{4}(\mathrm{aq})+\mathrm{BaCl}_{2}(\mathrm{aq}) \rightarrow \mathrm{KCl}(\mathrm{aq})+\mathrm{Ba}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s})
$$

To balance this equation, place a coefficient of 2 in front of $\mathrm{K}_{3} \mathrm{PO}_{4}$ to balance phosphate units. This requires a coefficient of 6 in front of KCl to balanced potassium atoms. Finally, a coefficient of 3 in front of $\mathrm{BaCl}_{2}$ will balance both the barium atoms and the chlorine atoms. The balanced equation is:

$$
2 \mathrm{~K}_{3} \mathrm{PO}_{4}(\mathrm{aq})+3 \mathrm{BaCl}_{2}(\mathrm{aq}) \rightarrow 6 \mathrm{KCl}(\mathrm{aq})+\mathrm{Ba}_{3}\left(\mathrm{PO}_{4}\right)_{2}(\mathrm{~s})
$$

b) This reaction between an elemental form and an oxoacid should suggest a single displacement reaction of the general form $\mathrm{A}+\mathrm{BC} \rightarrow \mathrm{AC}+\mathrm{B}$ where A and B are elemental forms and BC and AC are compounds. The metal aluminum (Al) displaces hydrogen in the oxoacid to form elemental hydrogen, $\mathrm{H}_{2}(\mathrm{~g})$, and an ionic compound consisting of aluminum ions $\left(\mathrm{Al}^{3+}\right)$ ions and sulfate $\left(\mathrm{SO}_{4}{ }^{2-}\right)$ ions. This means that the formula of the compound formed between $\mathrm{Al}^{3+}$ and $\mathrm{SO}_{4}{ }^{2-}$ is $\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}$. Although this ionic compound contains a +3 cation and a -2 anion, suggesting it is insoluble, compounds containing sulfate tend to be soluble. The unbalanced equation is:

$$
\mathrm{Al}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \rightarrow \mathrm{H}_{2}(\mathrm{~g})+\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}(\mathrm{aq})
$$

To balance this equation, place a coefficient of 2 in front of Al to balance aluminum atoms and place a coefficient of 3 in front of $\mathrm{H}_{2} \mathrm{SO}_{4}$ to balance sulfate units. Finally, a coefficient of 3 in front of $\mathrm{H}_{2}$ will balance both the hydrogen atoms. The balanced equation is:

$$
2 \mathrm{Al}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \rightarrow 3 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{Al}_{2}\left(\mathrm{SO}_{4}\right)_{3}(\mathrm{aq})
$$

c) This is a reaction between a $\mathrm{C}_{\mathrm{x}} \mathrm{H}_{y} \mathrm{O}_{z}$ compound and oxygen so it is a combustion reaction that forms $\mathrm{CO}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ as products.

$$
\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \text { (unbalanced) }
$$

Start by balancing the carbon atoms by putting a coefficient of 4 in front of $\mathrm{CO}_{2}$. Since there are 10 H atoms on the reactant side and only 2 H atoms on the product side, a coefficient of 2 in front of $\mathrm{H}_{2} \mathrm{O}$ will balance hydrogen atoms.

$$
\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 4 \mathrm{CO}_{2}(\mathrm{~g})+5 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad(\mathrm{C} \text { and } \mathrm{H} \text { atoms balanced })
$$

Finally, balance the oxygen atoms. Since there are 3 O atoms on the reactant side and 13 O atoms on the product side, multiplying $\mathrm{O}_{2}$ by 6 will balance oxygen atoms.

$$
\mathrm{C}_{4} \mathrm{H}_{9} \mathrm{OH}(\mathrm{~g})+6 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 4 \mathrm{CO}_{2}(\mathrm{~g})+5 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \text { (all atoms balanced) }
$$

d) This reaction between an ionic compound and an oxoacid should suggest a double displacement reaction of the general form $\mathrm{AB}+\mathrm{CD} \rightarrow \mathrm{AD}+\mathrm{CB}$. In this case the metal copper ( Bi ) and hydrogen in the reactants switch places to form water and an ionic compound between copper and nitrate. Notice that the ionic compound reactant $(\mathrm{CuO})$ involves $\mathrm{Cu}^{2+}$. Since nitrate ion has a -1 charge, the correct formula for the ionic compound formed is $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}$. This combination of $\mathrm{a}+2$ cation and $\mathrm{a}-1$ anion is expected to soluble. This results in the unbalanced equation:

$$
\mathrm{CuO}(\mathrm{~s})+\mathrm{HNO}_{3}(\mathrm{aq}) \rightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Notice that the copper atoms and oxygen atoms are balanced. To balance this equation, place a coefficient of 2 in front of $\mathrm{HNO}_{3}$ to balance hydrogen atoms and the nitrate units. The balanced equation is:

$$
\mathrm{CuO}(\mathrm{~s})+2 \mathrm{HNO}_{3}(\mathrm{aq}) \rightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

e) The reaction of two elemental forms should suggest a combination reaction. Since a metal $(\mathrm{Al})$ is reacting with a nonmetal $\left(\mathrm{Br}_{2}\right)$ an ionic compound will form. Aluminum is expected to form an $\mathrm{Al}^{3+}$ ion and bromine is expected to form a $\mathrm{Br}^{-}$ion. The correct formula for the ionic compound formed is $\mathrm{AlBr}_{3}$. This combination of $\mathrm{a}+3$ cation and a -1 anion is expected to soluble. This results in the unbalanced equation:

$$
\mathrm{Al}(\mathrm{~s})+\mathrm{Br}_{2}(\mathrm{l}) \rightarrow \mathrm{AlBr}_{3}(\mathrm{aq})
$$

The aluminum atoms are balanced but there are 2 bromine atoms on the reactant side and 3 bromine atoms on the product side. Multiplying $\mathrm{Br}_{2}$ by $3 / 2$ will balance bromine atoms.

$$
\mathrm{Al}(\mathrm{~s})+3 / 2 \mathrm{Br}_{2}(\mathrm{l}) \rightarrow \mathrm{AlBr}_{3}(\mathrm{aq})
$$

The fractional coefficient in front of $\mathrm{Br}_{2}$ can be converted to the smallest whole number by multiplying by 2 . This requires that all other coefficients be multiplied by 2 in order to retain the atom balance. The resulting balanced equation is:

$$
2 \mathrm{Al}(\mathrm{~s})+3 \mathrm{Br}_{2}(\mathrm{l}) \rightarrow 2 \mathrm{AlBr}_{3}(\mathrm{aq})
$$
